#### Motivation and examples Problem definition

# Motivation

- Publish-subscribe systems need to guarantee the privacy and authenticity of the participants.
  - Interactive gaming, stock data distribution, video conferencing, etc.
- Most systems rely on symmetric key cryptography to multicast messages.
  - We refer to key being used as group key.
- Any user should have access to the data only during the time periods that the user is a member of the group.
  - Need to update group key when set of group members changes.

Motivation and examples Problem definition

### Key update cost models

- Minimize the number of update messages sent. Motivation: consume minimum resources at the server.
- Minimize the total routing cost of update messages. Motivation: reduce network traffic.
- We consider both update models.

Motivation and examples Problem definition

### Key update approaches

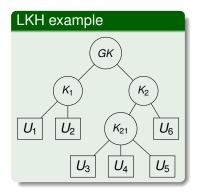

- Naive approach: update one member at a time using his/her public key.
- Logical key hierarchy.
  - A single group key for data communication.
  - A group controller distribute *auxiliary subgroup key* to the group members according to a key hierarchy.
  - Each member stores auxiliary keys coresponding to all the nodes in the path to the root in the hierachy.

Motivation and examples Problem definition

### Example of a logical key hierarchy

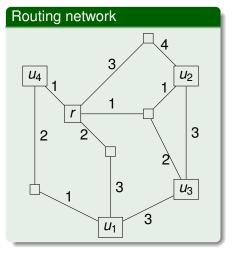

- *GK* is the group key.
- K's are auxiliary keys.
- Each user holds keys that lie along the path to the root.
  - U<sub>3</sub> has key GK, K<sub>2</sub>, K<sub>21</sub> and U<sub>3</sub>'s public key.
- When there is an update at a leaf, need to change group key.
  - View each leaf as a subgroup of users; whenever a user joins/leaves, an update occurs at the leaf.

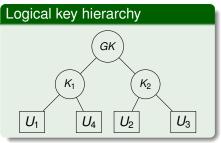

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへの

Motivation and examples Problem definition

### Example: routing cost of update messages

If  $u_2$  requests key update, the cost will be 2 + 3 + 4 + 4 = 13.

# **Problem input**

An instance of the Key Hierarchy Problem is given by the tuple (S, w, G, c).

- *S* is the set of group members.
- *w* : *S* → *Z* is the weight function (capturing the update probabilities).
- G = (V, E) is the underlying communication network with
  V ⊇ S ∪ {r} where r is a distinguished node representing the group controller.
- $c: E \rightarrow Z$  gives the cost of the edges in *G*.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへの

Motivation and examples Problem definition

### Cost of key hierarchy

- A hierarchy on a set X ⊆ S to be a rooted tree H whose leaves are the elements of X.
- Cost of a member x with respect to H is given by

$$\sum_{v \in V} \sum_{v \in V} M(T_v)$$

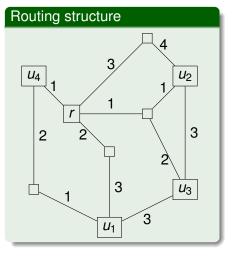

ancestor u of x child v of u

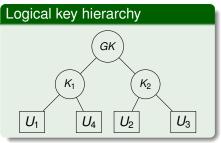

- $T_v$  is the set of leaves in the subtree of T rooted at v.
- *M*(*Y*) is the cost of multicasting from the root *r* to *Y* in *G*.
- Cost of a hierarchy *H* over *X* is the sum of the weighted costs of all the members of *X* with respect to *H*.

# Results for uniform multicast model

- Identical update probabilities: We compute the optimal key hierarchy in polynomial time.
- General update probabilities: We give a PTAS (polynomial time approximation scheme).
  - Cost of this key hierarchy is within 1 + ε times the cost of the optimal key hierarchy, where ε > 0 and can be arbitrarily small.

# Results for nonuniform multicast model

#### Hardness results:

- The Key Hierarchy Problem is NP-complete when group members have different weights and the routing network is a tree.
- The Key Hierarchy Problem is NP-complete when group members have the same weights and the routing netwrok is a general graph.

#### Approximation results:

- An 11-approximation algorithm when the routing network is a tree.
- A 75-approximation algorithm when the routing network is a general graph.

### Divide and conquer

#### Lemma

For any instance, there exists a 3-approximate binary hierarchy.

So we can focus on finding a good binary key hierarchy.

- Firstly, *partition* the member set into 2 subsets.
- Then find a "good" binary key hierarchy for each subset recursively.
- Lastly, *combine* these 2 binary key hierarchies.

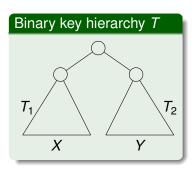

Keys of partitioning:

- Make close users "close" in the hierarchy.
- Balance the weight of binary hierarchy.

Key ingredients Approximation algorithm

### Combine logical key hierarchies

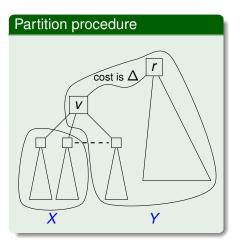

- Let *T*<sub>1</sub> be a "good" binary hierarchy for member set *X*.
- Let *T*<sub>2</sub> be a "good" binary hierarchy for member set *Y*.
- Define combine(T<sub>1</sub>, T<sub>2</sub>) to be the following. Add a new root r, and make T<sub>1</sub> the left subtree, T<sub>2</sub> the right subtree.

◆□ > ◆□ > ◆豆 > ◆豆 > 三日 のへで

Key ingredients Approximation algorithm

### Partition member set

- Assume the routing network is a tree, controller is the root, and members are the leaves.
- $W(S)/3 \le W(X), W(Y) \le 2W(S)/3$ , where  $S = X \cup Y$ and  $W(\cdot)$  is the total weight of the members in the set.

### Light approximate shortest-path tree (LAST)

Our approximation algorithm uses the elegant algorithm of Khuller-Raghavachari-Young for finding spanning trees that simultaneously approximates both the minimum spanning tree and the shortest path tree. An  $(\alpha, \beta)$ -LAST of a given weighted graph *G* is a spanning tree *T* of *G*, such that

- shortest path in *T* from root to any vertex is at most α times the shortest path from the root to the vertex in *G*,
- total weight of *T* is at most *β* times the minimum spanning tree of *G*.

# Approximating the multicast cost

- If the routing network is a graph, the optimum multicast to a member set is obtained by a minimum Steiner tree, computing which is NP-hard.
- There is an easy 2-approximation algorithm using a minimum spanning tree (MST) in the metric space defined by the routing graph.
- So we approximate *M*(*Y*) by the cost of MST connecting the root *r* to *Y* in the complete graph *G*(*Y*) whose vertex set is *S* ∪ {*r*} and the weight of edge (*u*, *v*) is the shortest path distance between *u* and *v* in the routing graph *G*.

#### ApproxGraph(S)

- If *S* is singleton, return trivial hierarchy with one node.
- Compute complete graph on S ∪ {root}; weight of (u, v) is the length of shortest path between u and v in the original routing graph.
- Compute minimum spanning tree on this complete graph.
- Compute an  $(\alpha, \beta)$ -LAST *L* of MST(*S*).
- (X, v) = partition(L).
- Let  $\Delta$  be the cost from root to partition node v. If  $\Delta \leq M(S)/5$ ,  $T_1 = \text{ApproxGraph}(X)$ . Otherwise,  $T_1 = \text{PTAS}(X)$ .  $T_2 = \text{ApproxGraph}(Y)$ .
- $T_2 = \operatorname{ApproxGraph}(Y)$ .
- Return **combine**( $T_1, T_2$ ).

◆□▶ ◆□▶ ◆□▶ ◆□▶ ●□□ のQ@

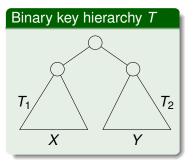

Key ingredients Approximation algorithm

### Proof sketch of constant approximation ratio

#### Theorem

Algorithm ApproxGraph is a constant-factor approximation.

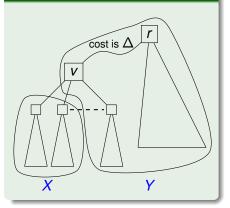

Proof uses induction on the number of members in *S*.

- *ALG*(*S*) cost of hierarchy produced by ApproxGraph.
- *OPT*(*S*) cost of optimal hierarchy.
- ALG(S) = ALG(X) + ALG(Y) + W(S) [M(X) + M(Y)].
- $OPT(S) \ge OPT(X) + OPT(Y)$ .

◆□▶ ◆□▶ ◆□▶ ◆□▶ ●□□ のQ@

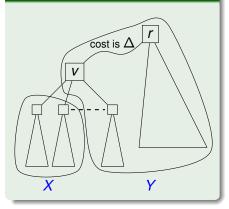

#### $(\alpha, \beta)$ -LAST of routing network

### Case 1: $\Delta > M(S)/5$

- Distance from *r* to any elem in X is bigger than Δ.
- This distance is close to shortest path in the original graph.
- Multicast cost to any subset of X is "roughly" the same. Use PTAS to get better approx on ALG(X).
- Apply induction hypothesis on *Y*.

#### $(\alpha, \beta)$ -LAST of routing network

Case 2:  $\Delta \leq M(S)/5$ 

• Apply induction hypothesis on both *X* and *Y*.

### **Open problems**

- Hardness result for uniform multicast cost but non-uniform key update probabilities.
- Dynamic maintenance of key hierarchies when members change update probabilities.
- Design key hierarchies where members have a bound on the number of auxiliary keys they store.
