**Question 1.** *Provide a summary of the contributions of this paper.* 

**Response:** 

**Question 2.** Derive equation (2). Your response should point out any assumptions the derivation is *making*.

 $\log p(\theta|\mathcal{D}) = \log p(\mathcal{D}_B|\theta) + \log p(\theta|\mathcal{D}_A) - \log p(\mathcal{D}_B)$ (2)

**Response:** 

**Question 3.** *Explain how formulation (3) is obtained from equation (2).* 

$$\mathcal{L}(\theta) = \mathcal{L}_B(\theta) + \sum_i \frac{\lambda}{2} F_i (\theta_i - \theta_{A,i}^*)^2$$
(3)

$$D_{e^{Sn^{0}}}^{F^{0}} \text{Fisher information matrix of } P_{\theta}$$

$$F = E D_{e^{I}}^{I} P_{e^{I}}^{I} = - E \left[ \nabla_{e^{I}} P_{e^{I}}^{I} P_{e^{I}}^{I} \right] \frac{1}{z - P_{\theta}}$$

Consider a probability dist. that depends on 
$$\Theta$$
  
 $P(Z|\Theta)$ ,  $P_{\Theta}(Z)$   
How much does  $\Theta$  affect  $P_{\Theta}$  on average? Consider  $\Theta \in \mathbb{R}^{d}$   
 $\underset{Z \sim P_{\Theta}}{\Vdash} \frac{\partial^{2}}{\partial \theta_{U}^{2}} \log P_{\Theta}(Z)$ 

Evaluate 
$$2^{WJ}$$
 derivative  $\hat{e}$   
 $\frac{\partial^{2}}{\partial \theta_{j}^{2} \partial \theta_{i}} \log P_{\theta}(z) = \frac{\partial}{\partial \theta_{j}} \frac{\partial_{\theta_{i}} P_{\theta}(z)}{P_{\theta}(z)}$   
 $= \frac{\partial_{\theta_{i}} \partial_{\theta_{i}} P_{\theta}(z)}{P_{\theta}(z)} - \frac{\partial_{\theta_{i}} P_{\theta}(z)}{P_{\theta}(z)} \frac{\partial_{\theta_{j}} P_{\theta}(z)}{P_{\theta}(z)}$   
 $= \frac{\partial^{2}_{\theta_{i}} \theta_{j} P_{\theta}(z)}{P_{\theta}(z)} - \partial_{\theta_{i}} \log P_{\theta}(z) \partial_{\theta_{j}} \log P_{\theta}(z)$   
 $\sum_{z \sim P_{\theta}} \frac{\partial_{\theta_{i}} \theta_{j}}{P_{\theta}(z)} = \frac{\sum_{z \sim P_{\theta}} \partial_{\theta_{i}} \log P_{\theta}(z)}{P_{\theta}(z)} - \frac{\sum_{z \sim P_{\theta}} \partial_{\theta_{i}} \log P_{\theta}(z)}{P_{\theta}(z)} - \frac{\sum_{z \sim P_{\theta}} \partial_{\theta_{i}} \log P_{\theta}(z)}{P_{\theta}(z)} \partial_{\theta_{j}} \log P_{\theta}(z)}$ 

## Limitations of the Empirical Fisher Approximation for Natural Gradient Descent

## Abstract

Natural gradient descent, which preconditions a gradient descent update with the Fisher information matrix of the underlying statistical model, is a way to capture partial second-order information. Several highly visible works have advocated an approximation known as the empirical Fisher, drawing connections between approximate second-order methods and heuristics like Adam. We dispute this argument by showing that the empirical Fisher—unlike the Fisher—does not generally capture second-order information. We further argue that the conditions under which the empirical Fisher approaches the Fisher (and the Hessian) are unlikely to be met in practice, and that, even on simple optimization problems, the pathologies of the empirical Fisher can have undesirable effects.

## 1 Introduction

Consider a supervised machine learning problem of predicting outputs  $y \in \mathbb{Y}$  from inputs  $x \in \mathbb{X}$ . We assume a probabilistic model for the conditional distribution of the form  $p_{\theta}(y|x) = p(y|f(x,\theta))$ , where  $p(y|\cdot)$  is an exponential family with natural parameters in  $\mathbb{F}$  and  $f \colon \mathbb{X} \times \mathbb{R}^D \to \mathbb{F}$  is a prediction function parameterized by  $\theta \in \mathbb{R}^D$ . Given N iid training samples  $(x_n, y_n)_{n=1}^N$ , we want to minimize

$$\mathcal{L}(\theta) := -\sum_{n} \log p_{\theta}(y_n | x_n) = -\sum_{n} \log p(y_n | f(x_n, \theta)).$$
(1)

This framework covers common scenarios such as least-squares regression  $(\mathbb{Y} = \mathbb{F} = \mathbb{R} \text{ and } p(y|f) = \mathcal{N}(y; f, \sigma^2)$  with fixed  $\sigma^2$ ) or C-class classification with cross-entropy loss  $(\mathbb{Y} = \{1, \ldots, C\}, \mathbb{F} = \mathbb{R}^C$  and  $p(y = c|f) = \exp(f_c) / \sum_i \exp(f_i)$ ) with an arbitrary prediction function f. Eq. (1) can be minimized by gradient descent, which updates  $\theta_{t+1} = \theta_t - \gamma_t \nabla \mathcal{L}(\theta_t)$  with step size  $\gamma_t \in \mathbb{R}$ . This update can be *preconditioned* with a matrix  $B_t$  that incorporates additional information, such as local curvature,  $\theta_{t+1} = \theta_t - \gamma_t B_t^{-1} \nabla \mathcal{L}(\theta_t)$ . Choosing  $B_t$  to be the Hessian yields Newton's method, but its computation is often burdensome and might not be desirable for non-convex problems. A prominent variant in machine learning is *natural gradient descent* [NGD; Amari, 1998]. It adapts to the *information geometry* of the problem by measuring the distance between parameters with the Kullback–Leibler divergence between the resulting distributions rather than their Euclidean distance, using the Fisher information matrix (or simply "Fisher") of the model as a preconditioner,

$$\mathbf{F}(\theta) := \sum_{n} \mathbb{E}_{p_{\theta}(y|x_{n})} \left[ \nabla_{\theta} \log p_{\theta}(y|x_{n}) \nabla_{\theta} \log p_{\theta}(y|x_{n})^{\top} \right].$$
(2)

While this motivation is conceptually distinct from approximating the Hessian, the Fisher coincides with a generalized Gauss-Newton [Schraudolph, 2002] approximation of the Hessian for the problems presented here. This gives NGD theoretical grounding as an approximate second-order method.

A number of recent works in machine learning have relied on a certain approximation of the Fisher, which is often called the *empirical Fisher (EF)* and is defined as

$$\mathbf{F}(\theta) := \sum_{n} \nabla_{\theta} \log p_{\theta}(y_{n} | x_{n}) \nabla_{\theta} \log p_{\theta}(y_{n} | x_{n})^{\top}.$$
