

Let us now look at implementing graph algorithms in MapReduce.

264

Why Graphs?

- Discussion is based on the book and slides by Jimmy Lin and Chris Dyer
- Analyze hyperlink structure of the Web
- Social networks
 - Facebook friendships, Twitter followers, email flows, phone call patterns
- Transportation networks
 - Roads, bus routes, flights
- Interactions between genes, proteins, etc.

265

What is a Graph?

- $G = (V, E)$
 - V : set of vertices (nodes)
 - E : set of edges (links), $E \subseteq V \times V$
- Edges can be directed or undirected
- Graph might have cycles or not (acyclic graph)
- Nodes and edges can be annotated
 - E.g., social network: node has demographic information like age; edge has type of relationship like friend or family

266

Graph Problems

- Graph search and path planning
 - Find driving directions from A to B
 - Recommend possible friends in social network
 - How to route IP packets or delivery trucks
- Graph clustering
 - Identify communities in social networks
 - Partition large graph to parallelize graph processing
- Minimum spanning trees
 - Connected graph of minimum total edge weight

267

More Graph Problems

- Bipartite graph matching
 - Match nodes on “left” with nodes on “right” side
 - E.g., match job seekers and employers, singles looking for dates, papers with reviewers
- Maximum flow
 - Maximum traffic between source and sink
 - E.g., optimize transportation networks
- Finding “special” nodes
 - E.g., disease hubs, leader of a community, people with influence

268

Graph Representations

- Usually one of these two:
 - Adjacency matrix
 - Adjacency list

269

Adjacency Matrix

- Matrix M of size $|N|$ by $|N|$
 - Entry $M(i,j)$ contains weight of edge from node i to node j ; 0 if no edge

| | 1 | 2 | 3 | 4 |
|---|---|---|---|---|
| 1 | 0 | 1 | 0 | 1 |
| 2 | 1 | 0 | 1 | 1 |
| 3 | 1 | 0 | 0 | 0 |
| 4 | 1 | 0 | 1 | 0 |

Example source: Jimmy Lin

270

Properties

- Advantages
 - Easy to manipulate with linear algebra
 - Operation on outlinks and inlinks corresponds to iteration over rows and columns
- Disadvantage
 - Huge space overhead for sparse matrix
 - E.g., Facebook friendship graph

271

Adjacency List

- Compact row-wise representation of matrix

| | 1 | 2 | 3 | 4 |
|---|---|---|---|---|
| 1 | 0 | 1 | 0 | 1 |
| 2 | 1 | 0 | 1 | 1 |
| 3 | 1 | 0 | 0 | 0 |
| 4 | 1 | 0 | 1 | 0 |

1: 2, 4
 2: 1, 3, 4
 3: 1
 4: 1, 3

272

Properties

- Advantages
 - More space-efficient
 - Still easy to compute over outlinks for each node
- Disadvantage
 - Difficult to compute over inlinks for each node
- Note: remember inverse Web graph discussion

273

Parallel Breadth-First Search

- Case study: single-source shortest path problem
 - Find the shortest path from a source node s to all other nodes in the graph
- For non-negative edge weights, Dijkstra's algorithm is the classic sequential solution
 - Initialize distance $d[s]=0$, all others to ∞
 - Maintain priority queue of nodes sorted by distance
 - Remove first node u from queue and update $d[v]$ for each node v in adjacency list of u if (1) v is in queue and (2) $d[v] > d[u] + \text{weight}(u,v)$

274

Dijkstra's Algorithm Example

Example from Jimmy Lin's presentation

275

Dijkstra's Algorithm Example

Dijkstra's Algorithm Example

278

Dijkstra's Algorithm Example

279

Dijkstra's Algorithm Example

280

Parallel Single-Source Shortest Path

- Priority queue is core element of Dijkstra's algorithm
 - No global shared data structure in MapReduce
- Dijkstra's algorithm proceeds sequentially, node by node
 - Taking non-min node could affect correctness of algorithm
- Solution: perform parallel breadth-first search

281

Parallel Breadth-First Search

- Start at source s
- In first round, find all nodes reachable in one hop from s
- In second round, find all nodes reachable in two hops from s , and so on
- Keep track of min distance for each node
 - Also record corresponding path
- Iterations stop when no shorter path possible

282

BFS Visualization

Example from Jimmy Lin's presentation

283

MapReduce Code: Single Iteration

```

map(nid n, node N)           // N stores node's current min distance and adjacency list
d = N.distance
emit(nid n, N)              // Pass along graph structure
for all nid m in N.adjacencyList do
  emit(nid m, d + w(n,m))   // Emit distances to reachable nodes

reduce(nid m, [d1,d2,...])
dMin = ∞; M = ∅
for all d in [d1,d2,...] do
  if isNode(d) then
    M = d                    // Recover graph structure
  else if d < dMin then     // Look for min distance in list
    dMin = d
M.distance = dMin          // Update node's shortest distance
emit(nid m, node M)

```

284

Overall Algorithm

- Need driver program to control the iterations
- Initialization: SourceNode.distance = 0, all others have distance=∞
- When to stop iterating?
- If all edges have weight 1, can stop as soon as no node has ∞ distance any more
 - Can detect this with Hadoop counter
- Number of iterations depends on graph diameter
 - In practice, many networks show the small-world phenomenon, e.g., six degrees of separation

285

Dealing With Diverse Edge Weights

- “Detour” path can be shorter than “direct” connection, hence cannot stop as soon as all node distances are finite
- Stop when no node’s shortest distance changes any more
 - Can be detected with Hadoop counter
 - Worst case: $|N|$ iterations

Example from Jimmy Lin's presentation

286

MapReduce Algorithm Analysis

- Brute-force approach that performs many irrelevant computations
 - Computes distances for nodes that still have infinity distance
 - Repeats previous computations inside “search frontier”
- Dijkstra’s algorithm only explores the search frontier, but needs the priority queue

287

Typical Graph Processing in MapReduce

- Graph represented by adjacency list per node, plus extra node data
- Map works on a single node u
 - Node u 's local state and links only
- Node v in u 's adjacency list is intermediate key
 - Passes results of computation along outgoing edges
- Reduce combines partial results for each destination node
- Map also passes graph itself to reducers
- Driver program controls execution of iterations

288

PageRank Introduction

- Popularized by Google for evaluating the quality of a Web page
- Based on [random Web surfer](#) model
 - Web surfer can reach a page by jumping to it or by following the link from another page pointing to it
 - Modeled as random process
- Intuition: important pages are linked from many other (important) pages
 - Goal: find pages with greatest probability of access

289

PageRank Definition

- PageRank of page n :
 - $P(n) = \alpha \frac{1}{|V|} + (1 - \alpha) \sum_{m \in L(n)} \frac{P(m)}{C(m)}$
 - $|V|$ is number of pages (nodes)
 - α is probability of random jump
 - $L(n)$ is the set of pages linking to n
 - $P(m)$ is m 's PageRank
 - $C(m)$ is m 's out-degree
- Definition is recursive
 - Compute by iterating until convergence (fixpoint)

290

Computing PageRank

- Similar to BFS for shortest path
- Computing $P(n)$ only requires $P(m)$ and $C(m)$ for all pages linking to n
 - During iteration, distribute $P(m)$ evenly over outlinks
 - Then add contributions over all of n 's inlinks
- Initialization: any probability distribution over the nodes

291

PageRank Example

292

PageRank Example

293

PageRank in MapReduce

294

MapReduce Code

```

map(nid n, node N)           // N stores node's current PageRank and adjacency list
  p = N.pageRank / |N.adjacencyList|
  emit(nid n, N)             // Pass along graph structure
  for all nid m in N.adjacencyList do
    emit(nid m, p)          // Pass PageRank mass to neighbors

reduce(nid m, [p1,p2,...])
  s=0; M = ∅
  for all p in [p1,p2,...] do
    if isNode(p) then
      M = p                  // Recover graph structure
    else
      s += p                 // Sum incoming PageRank contributions
  M.pageRank = α/|V| + (1-α)·s
  emit(nid m, node M)
  
```

295

Dangling Nodes

- Consider node x with no outgoing links
 - $P(x)$ is not passed to any other node, hence gets “lost” in the Map phase
- Need to correct for the missing probability mass
 - Model: assume dangling page links to all pages
 - Mathematically equivalent to

$$P(n) = \alpha \frac{1}{|V|} + (1 - \alpha) \left(\frac{\delta}{|V|} + \sum_{m \in L(n)} \frac{P(m)}{C(m)} \right)$$
 - δ : missing PageRank mass due to dangling nodes

296

PageRank with Dangling Nodes

- Challenge: need δ , which is the sum over the current page ranks of dangling nodes
 - MR-job1: compute δ
 - MR-job2: compute new PageRank using δ
- Alternative computations?
 - Order inversion pattern to make sure δ is available in all reduce tasks

297

Number of Iterations

- PageRank computation iterates until convergence
 - PageRank of all nodes no longer changes (or is within small tolerance)
 - Needs to be checked by driver
- Original PageRank paper: 52 iterations until convergence on graph with 322 million edges
 - Highly dependent on data properties

298

General Graph Processing Issues

- Sequential algorithms often use **global** data structure for efficiency
- In MapReduce with adjacency list representation, information can only be passed **locally** to or from direct neighbors
 - But can pre-compute other data structures, e.g., two-hop neighbors
- Presented algorithms have Map output of $O(\#edges)$, which works well for sparse graphs

299

General Graph Processing Issues

- Partitioning of graph into chunks strongly affects effectiveness of combiners
 - Often best to keep well-connected components together
- Numerical stability for large graphs
 - PageRank of individual page might be so small that it underflows standard floating point representation
 - Can work with logarithm-transformed numbers instead
