

Functions Recursion

C++ functions

- ☉ **Declare/prototype**

```
int myfunction (int );
```

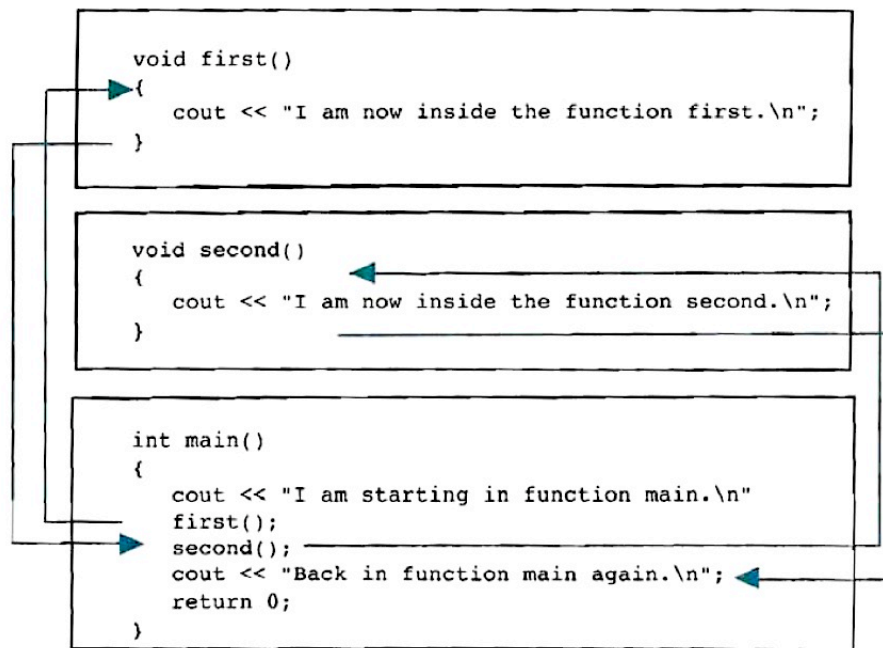

- ☉ **Define**

```
int myfunction (int x){  
    int y = x*x;  
    return y;  
}
```

- ☉ **Call**

```
int a;  
a = myfunction (7);
```

function call flow

types

- ⊗ type of function (of the return value)
 - `double myfunction (....)`
- ⊗ type of arguments
 - `double myfunction (int a, double b, char c)`
- ⊗ the types have to be consistent between declaration, definition and call

function arguments

CALL

```
area = PI * square(radius);
```

100

10

```
double square(double number)
{
    return number * number;
}
```

DEFINITION

arguments by value

- ⊗ value is copied to parameter/argument
- ⊗ parameters have the scope the function
 - same as a local variable

return

- ⦿ returns the function output value to the call instruction

- has to match function output type

```
int myfunction (int x){  
    int y = x*x;  
    return y;  
}
```

- ⦿ terminates the function

- even if there are more statements to execute

Argument default value

- if no argument is given at the call, use a default value

- default value given in function definition

```
double log5(double x=125){...  
  
    ...  
}
```

Scope: local and global

- ⦿ global : define outside any function
 - visible everywhere (preserve value)
- ⦿ local : define inside a function (or block)
 - invisible outside the definition block

Static variables

- ⦿ static local variables do not get erased when function/ block terminates
- ⦿ the next time the function is called, a static variable still has the previous value
 - initialized only one time

```
int function (int param){
    static double myvar=0;//initialization
    happens only at the first function call
    ... do something ...
}
```

Overload function names

- ⦿ myfunction does $y = 2*x_1 - 3*x_2$
 - I want it to work for doubles and int types
- ⦿ `int myfunction (int, int)`
- ⦿ `double myfunction (double, double)`
- ⦿ `double myfunction (int, double)`
- ⦿ `double myfunction (double, int)`

Arguments by reference

- ⦿ usually (call by value), if the argument passed to the function changes value inside the function, the variable used as argument does not.

```
//call
int a=0,b=0;
b = f1(a); //now a=0, b=1

//function definition
int f1 (int x){
    x = x +1;
    return x;
}
```

- ⦿ to modify the variable used as argument at the call, pass the argument by reference

```
//call
int a=0,b=0;
b = f2(a); //now a=1, b=1

//function definition
int f2 (int& x){
    x = x +1;
    return x;
}
```

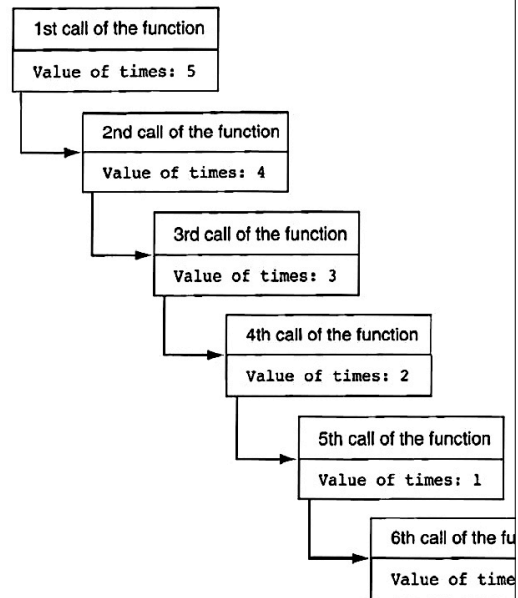

Recursive calls

Recursion of a function

- ⊗ A function that calls itself
 - OR cyclic: function f calls function g; function g calls function f
- ⊗ Creates a stack of calls
- ⊗ Calls terminate in the reverse order of calling
- ⊗ Local variables are defined independently for each call

Recursion: flow

```
void message(int times){  
    if (times>0){  
        cout<<"call t="<<times<<"\n";  
        message(times-1);  
    }  
}
```

Solving a problem recursively

- ④ recognize recursive/inductive nature
 - many problems easier to solve with a loop
- ④ build up the recursion mechanism
- ④ follow the principle of mathematical induction
- ④ most often, find an "invariant" operation
 - can be a math formula
 - can be an inductive form
 - do one step of it, then call the recursion (or the other way)
- ④ look carefully at the base cases

Sum of first n integers

- ⦿ $S(n) = 1 + 2 + 3 + 4 + \dots + n = n(n+1)/2$
- ⦿ induction : $S(n) = S(n-1) + n = (n-1)*n/2 + n = n(n+1)/2$

Sum of first n integers

- ⦿ $S(n) = 1 + 2 + 3 + 4 + \dots + n = n(n+1)/2$
- ⦿ induction : $S(n) = S(n-1) + n = (n-1)*n/2 + n = n(n+1)/2$

- ⦿ recursion

```
int sum (int n){  
    if (n<0) {  
        cout<<"ERROR, negative";  
        return -1;  
    }  
    if (n==0) return 0;  
    return n + sum(n-1);  
}
```

Factorial

- $n! = 1 * 2 * 3 * \dots * n$
- induction: $n! = n * (n-1)!$
 - $1! = 0! = 1$
- can be very very large
 - $10! = 3628800$
 - $50! \approx 3.0414 * 10^{64}$

Factorial

```
long factorial (long n){
    cout<< "call: factorial("<<n<<")\n";
    int out;
    if(n<=1) out=1;
    else out = n*factorial(n-1);
    cout<<"return: factorial("<<n<<")\n";
    return out;
}
```

Tower of Hanoi

- three towers/rods A, B, C
- A contains pegs 1 to n, in order, n at the bottom
- B, C empty
- TASK: move all pegs to A such that
 - a peg at a time
 - only top peg of a tower can move
 - peg can "sit" only on higher value pegs

Tower of Hanoi

Tower of Hanoi

Tower of Hanoi

Tower of Hanoi

Tower of Hanoi

- function f : moves top k pegs from tower X to tower Y
 - leaves all pegs existing on Z and Y unmoved
 - leaves all pegs on tower X below top k unmoved
- function f is recursive
 - moves top $k-1$ pegs from X to Z (recursive call)
 - moves k peg from X to Y
 - moves top $k-1$ pegs from Z to Y (recursive call)

Euclid GCD

- ⊗ given positive integers a and b
 - find $d = \text{GCD}(a, b)$
 - find integers m, n such that $a \cdot m + b \cdot n = d$. Do they always exist?
- ⊗ recursion: if $a > b$ and $a = q \cdot b + r$ then
 - $\text{GCD}(a, b) = \text{GCD}(b, r)$
 - what about m and n ?

Euclid GCD: find linear coefficients

- ⊗ given positive integers a and b
 - find $d = \text{GCD}(a, b)$
 - find integers m, n such that $a \cdot m + b \cdot n = d$. Do they always exist?
- ⊗ recursion: if $a > b$ and $a = q \cdot b + r$ then
 - $\text{GCD}(a, b) = \text{GCD}(b, r)$
 - $m_{(ab)} = n_{(br)}$
 - $n_{(ab)} = m_{(br)} - q \cdot n_{(br)}$

Fibonacci numbers

- ⊗ Problem defined with recursion

- ⊗ $F(n+2) = F(n) + F(n+1)$

- ⊗ $F(0) = 0; F(1) = 1$

```
int Fibonacci (int n){  
    if (n<=1) return n;  
    else return Fibonacci(n-1) + Fibonacci(n-2);  
}
```

Count characters

- ⊗ preview the notion of ARRAY

- ⊗ `char s[200]; //array of 200 characters`

- different type than class `string`

- ⊗ can be accessed as `s[0], s[1], ..., s[199]`

- `s[0]='H'; s[1]='e'; s[2]='l'; s[3]='l'; s[4]='o';`

- `char a = s[3];`

- ⊗ works for any type

- `double d[10]; int i[100];`

- ⊗ C++ does not check for array bounds !!

Count characters

- ⦿ start counting at position 1
 - record 1 if character find,
 - keep looking at next position
- ⦿ can be a loop
- ⦿ can be a recursion

Binary search

- ⦿ Find a specific value V in a sorted array $A[]$
- ⦿ Start with array indices $i=0$, $j=\text{last}$, $m=\text{middle}$
- ⦿ Compare $A[m]$ to V and decide where in the array to look next
 - recursive call
 - or a loop
- ⦿ Why binary search and not simply check all elements ?

Binary search

- ⌚ How long is going to take? (worst case)
- ⌚ In algorithms, how long means how many steps/instructions
 - as a function of input n = size of array
- ⌚ we dont want an exact time/value
 - "linear" = like n = about $\text{CONSTANT} * n$
 - "quadratic" = like n^2 = about $\text{CONSTANT} * n^2$
 - $\text{CONST} * \log n$, $\text{CONST} * n * \log n$, etc
- ⌚ Binary Search takes $\text{CONSTANT} * \log(n)$ steps, in worst case
